Uncovering simultaneous breakthroughs with a robust measure of disruptiveness

Munjung Kim[1]†, Sadamori Kojaku[2], Yong-Yeol Ahn[1]*†

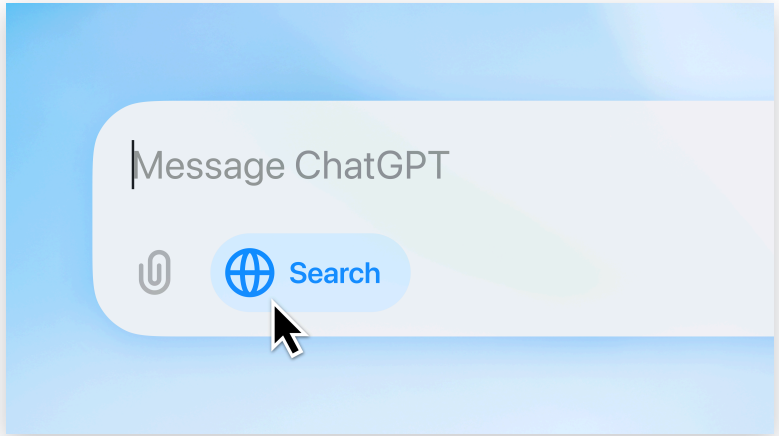

Progress in science and technology is punctuated by disruptive innovation and breakthroughs. To understand disruptive innovations and their drivers, the ability to operationalize and estimate "disruptiveness" is critical. Yet, this task remains difficult because scientific influence propagates through both direct and indirect citation paths, and discoveries are often fragmented across multiple papers. Here, we introduce an embedding-based metric of disruptiveness. When applied to large-scale publication data, the measure not only reliably identifies canonical breakthroughs, such as Nobel Prize–winning papers, but also finds simultaneous disruptions that eluded standard approaches. By enabling more robust identification of disruptive innovations and simultaneous discoveries, our method facilitates more accurate attribution of transformative contributions while providing insights into the mechanisms driving scientific breakthroughs.

Large teams develop and small teams disrupt science and technology

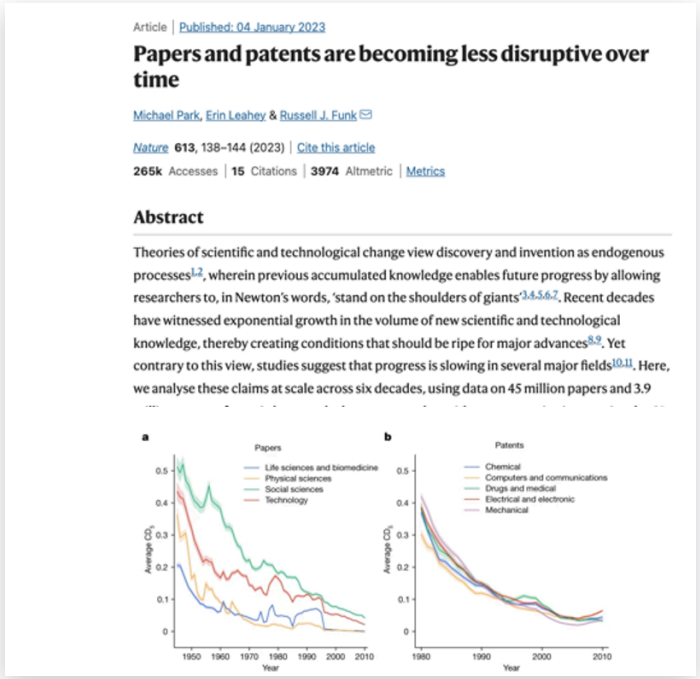

Lingfei Wu, Dashun Wang & James A. Evans

Nature **566**, 378–382 (2019) | Cite this article

119k Accesses | **289** Citations | **2580** Altmetric | Metrics

Abstract

One of the most universal trends in science and technology today is the growth of large teams in all areas, as solitary researchers and small teams diminish in prevalence[1,2,3]. Increases in team size have been attributed to the specialization of scientific activities[3], improvements in communication technology[4,5], or the complexity of modern problems that require interdisciplinary solutions[6,7,8]. This shift in team size raises the question of whether and how the character of the science and technology produced by large teams differs from that of small teams. Here we analyse more than 65 million papers, patents and software products that span the period 1954–2014, and demonstrate that across this period smaller teams have

Abstract

Theories of scientific and technological change view discovery and invention as endogenous processes[1,2], wherein previous accumulated knowledge enables future progress by allowing researchers to, in Newton's words, 'stand on the shoulders of giants'[3,4,5,6,7]. Recent decades have witnessed exponential growth in the volume of new scientific and technological knowledge, thereby creating conditions that should be ripe for major advances[8,9]. Yet contrary to this view, studies suggest that progress is slowing in several major fields[10,11]. Here, we analyse these claims at scale across six decades, using data on 45 million papers and 3.9

Abstract

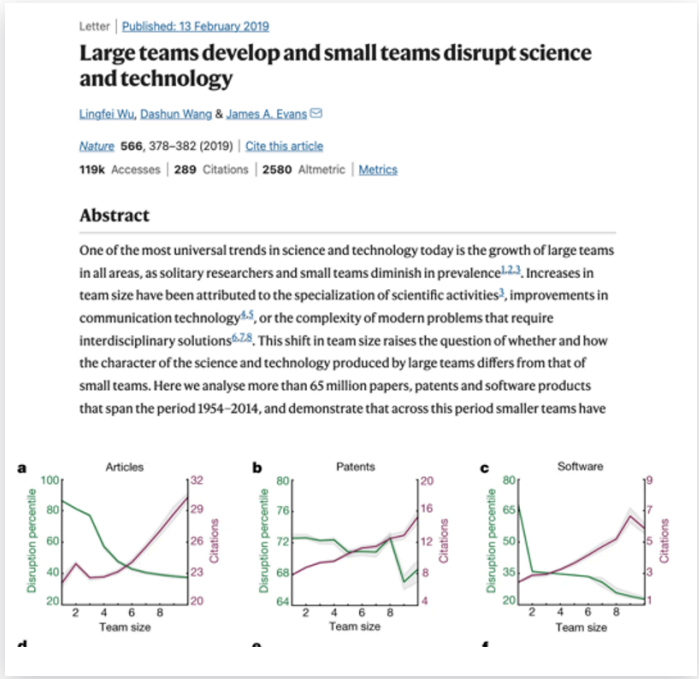

Theories of innovation emphasize the role of social networks and teams as facilitators of breakthrough discoveries[1,2,3,4]. Around the world, scientists and inventors are more plentiful and interconnected today than ever before[4]. However, although there are more people making discoveries, and more ideas that can be reconfigured in new ways, research suggests that new ideas are getting harder to find[5,6]—contradicting recombinant growth theory[7,8]. Here we shed light on this apparent puzzle. Analysing 20 million research articles and 4 million patent applications from across the globe over the past half-century, we begin by documenting the rise of remote collaboration across cities, underlining the growing

PRL Showcases Milestone Papers

Physical Review Letters has published many important papers during its 50-year history. As part of the *Physical Review Letters* 50th anniversary, former editor-in-chief Martin Blume is compiling a series of "Milestone Letters," showcasing some significant papers from each year of the journal, starting in 1958 and continuing through 2000.

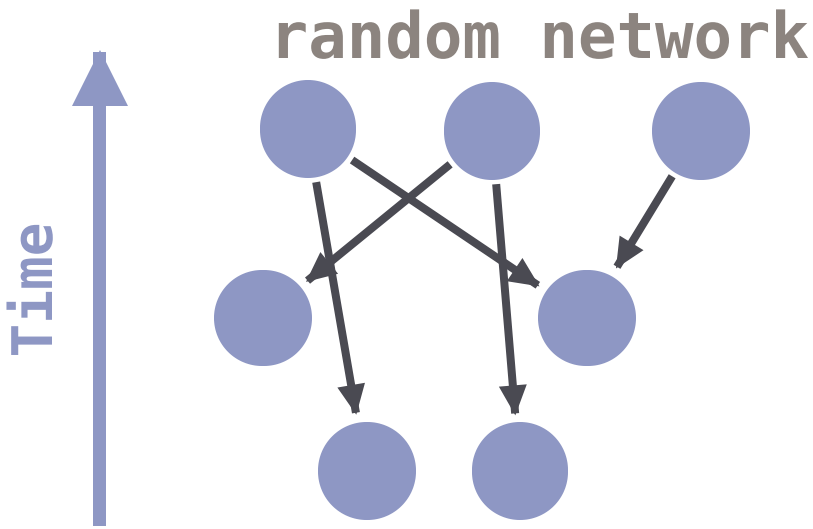

The "milestone letters" are papers that made important contributions to physics, announced significant discoveries, or started new areas of research. Many of these papers report research that resulted in Nobel prizes for their authors. The series covers a diverse range of subfields, and also gives a glimpse into the history and development of physics over the past 50 years.

Physical Review Letters started as a separate journal in 1958 as a way to quickly publish short research papers that had been published as letters to the editor in the *Physical Review*. Right from the start of the
